ABSTRACT

Background: Bronchial asthma Affecting 1-18% of children in different countries, it widely distributed chronic respiratory disease. vitamin-D increase calcium absorption from the gastrointestinal tract, determines bone health and regulates neuromuscular function. In addition, vitamin-D is a potent immune system regulator, and it has a potential role in various allergic diseases.

Aim of the work: To estimate the association between asthma and Vitamin-D in pediatrics.

Patients and methods: The present work is a case control study included 150 [100 asthmatic children and 50 healthy control] children aged between 5 and 12 years. Serum 25- hydroxy vitamin-D levels were evaluated and compared between two groups. Association between vitamin-D and pulmonary function was studied in asthmatic children.

Results: Cases had significantly lower values of FEV1%, FEV1/FVC ratio and vitamin-D levels when compared to controls [53.20±6.27, 68.64±4.42, 24.44±20.92 vs 126.44±10.15, 107.20±5.05 and 84.25±41.79 successively]. In addition, vitamin-D was positively and significantly correlated with pulmonary function tests [FEV1% and FEV1/FVC ratio].

Conclusion: Children with bronchial asthma suffered from marked reduction of vitamin-D which correlated with asthma severity.

Keywords: Bronchial Asthma; Children; Lung function; Vitamin-D; Correlation.

INTRODUCTION

Bronchial Asthma is a heterogeneous condition with hallmark chronic airway inflammation with variable expiratory airflow limitation; clinically, there was wheezy chest, shortness of breath and cough; these symptoms vary from time to time in frequency and intensity [1].

Increased prevalence of bronchial asthma may be explained by different etiologies; i.e., environmental [air pollution, different allergens, weather changes], lifestyle and dietary factors [2].

Hallmark of bronchial asthma is airway obstruction due to interaction between inflammatory mediators, immune cells and impaired immunogenic tolerance [3].

Vitamin-D play important role in neuromuscular function, hormone secretion [insulin] and calcium absorption from gastrointestinal tract [GIT]; in immune system, vitamin-D is a potent regulator and proposed to play a major role in different allergic diseases [4].

However, the existence of a link between vitamin-D and bronchial asthma or allergy need further investigation [5].

AIM OF THE WORK

To estimate the association between asthma and Vitamin-D in pediatrics.

PATIENTS AND METHODS

Case control study included 150 children in number aged between 5 and 12 years old at Pediatric department [outpatient and inpatient] of New Damietta faculty of medicine, Al-Azhar University; in two working days per week from 1/1/2018 to 31/12/2018.

One Hundred of them were suffering from bronchial asthma and 50 were healthy; age and sex matched children taken as a control group. Children with the following criteria were included in the present work: 1) Children known to be asthmatics according to GINA [Global Initiative for Asthma Guidelines] 2017. On the other side, children with one or more of the following were excluded from the study: 1) Children having chest diseases rather than asthma; 2) rickets; 3) apparent congenital anomalies; 4) Chronic liver, kidney, endocrine diseases; 5) on vitamin-D supplementation for the past one year; 6) medication that affect vitamin-D as phenobarbital, carbamazepine, phenytoin, clotrimazole, ketoconazole, rifampin and isoniazid.

Collected data included child’s demographics, anthropometric measurements and residence. In addition, details of sun exposure during the last month [duration of exposure per day and time of exposure] were measurement and documented [6].

3 ml of venous blood were collected in a plain tube under complete aseptic technique for each participant. Each sample was centrifuged and serum was separated and stored at -20°C till analysis. The sample was analyzed for the following tests: serum vitamin-D levels, complete blood count [CBC] for eosinophilia as well as total and differential WBCs count.

25-Hydroxy Vitamin-D values were measured by ELISA kit [KAP 1971/F1, Dia source immunoassays S.A] and values expressed in ng/ml. Serum level was classified as the following: deficient [<20 ng/mL], insufficient [20-30 ng/mL] and sufficient [>30 ng/mL] [7].

Pulmonary function tests were studied according to guidelines by the American Thoracic Society 2007 by using diagnostic spirometry [ZAN Mebgerate GmbH with abuilt-in computer] manufactured by nd Medizintechnik AG, 8005 Zurich, Switzerland [8].

Statistical analysis: A pre-formed excel sheet was used in collection of data according to standard prepared questionnaires. Then, data were transferred to statistical package for social science for analysis. The use version of SPSS was 22 [SPSS, Inc. Chicago, IL, USA]. Data were presented in the form of mean ± standard deviation [SD] for numerical normally distributed data and expressed in the form of numbers and percentage for qualitative variables. Student t-test, and Chi-square were used for comparison between groups. The correlations were analyzed by Pearson correlation coefficients. A p-value < 0.05 was considered significant.

RESULTS

100 asthmatic children and 50 healthy controls were included in the present work, and there was no significant difference between cases and
controls regarding patient age or sex [Table 1].

In addition, they were comparable as regard to their weight, height and body mass index (BMI). On the other side, cases had significantly lower values of FEV1%, FEV1/FVC ratio and vitamin-D levels when compared to controls [53.20±6.27, 68.64±4.42, 24.44±20.92 vs 126.44±10.15, 107.20±5.05 and 84.25±41.79 successively] [Table 2].

Furthermore, there was significant increase of asthma with deficient and insufficient vitamin-D levels [45.0%, 38.0% vs 0.0% and 20.0% respectively] and vitamin-D children were sufficient in controlled groups [17.0% vs 80.0% respectively] [Table 3].

Finally, there were a significant positive correlation between serum levels of vit. D, FEV1% and FEV1/FVC ratio in asthmatic children [Table 4], as there was a significant reduction of pulmonary function tests [FEV1% and FEV1/FVC ratio] in vitamin-D deficient children when compared to children with insufficient or sufficient vitamin-D levels and in children with insufficient vitamin-D when compared to those with sufficient vitamin-D [Table 5].

DISCUSSION

Bronchial Asthma in children is one of the commonest respiratory diseases all over the world. Vitamin-D, being fat-soluble vitamin and a steroid hormone plays a functional role to increase absorption of calcium and maintains bone health.

Reduced concentrations of vitamin-D play role in different cardiovascular disorders, development of inflammation & infectious diseases, diminished physical functions, allergy and all-cause mortality[9]. Relation between bronchial asthma and vitamin-D remains controversial. Thus, the present research aimed to estimate serum 25-hydroxy vitamin-D
levels in children with asthma and investigate the role of vitamin-D in those children. Vitamin-D was significantly reduced in asthmatic children. In addition, 45% of the asthmatic children were vitamin-D deficient. One study from Thai reported that, 64% of children with bronchial asthma were vitamin-D deficient[10].

In the present work, sun exposure was significantly reduced in asthmatic patients. This could be attributed to more time spent indoor by asthmatic children because childhood bronchial asthma frequently leads to personal activity limitation and high school absence rate[11].

We could say that, in the present work, vitamin-D levels positively correlated with pulmonary function tests. The pathogenic role of vitamin-D could be explained in several ways: first, due to immune deficiency as it has been associated to other many immunological diseases such as Cron’s disease, inflammatory bowel disease, diabetes mellitus, multiple sclerosis or rheumatoid arthritis[10, 11]. Second; vitamin-D had a modulatory role on the immune system; for example, it could promote sensitivity of steroids and down regulate the inflammation state by cytokine production or alternation in gene expression; the action which could affect airway directly. Third; vitamin-D receptors were found in the airway and vitamin-D deficiency could lead to failure in inflammatory state turning off, after acute inhalational insult, and upregulation of inflammatory mediators such as prostaglandin, leukotriene and macrophage activity[12, 13]. Results of the present trial agree with previous studies, reported that, children with good pulmonary function tests [FEV1%] had higher values of serum 25(OH) D[14, 15]. In addition, vitamin-D deficiency could be associated with irreversible loss of lung function due to airway remodeling with structural changes of airway walls caused by recurrent injury and repair processes[16]. Other studies could correlate asthma severity to reduced vitamin-D levels[10, 17, 18]. Thus, confirming its role in pathogenesis of bronchial asthma.

In conclusion, vitamin-D was significantly lower among asthmatic children when compared to healthy controls, and there was significant relationship between vitamin-D levels and pulmonary function tests. Thus, routine measurement of vitamin-D in asthmatic children is advocated. However, future studies were needed to examine the role of vitamin-D supplementation on the bronchial asthma in pediatrics.
